Streaming

- · Continuous data flow
 - "Unbounded streams of data"
- Usually uses a message distribution system
 - JMS, Apache Kafka, ZeroMQ, MQTT
- An unbounded set of events with time
 - -<t1, E1>, <t2, E2>,, <tn, En>,

Stream processing categorization

- · Simple event processing
 - Working on an event at a time
 - e.g. filter out all events where the wind speed > 50 mph
- · Event stream processing
 - Time-based processing of a single stream of events
 - Average wind speed over the last hour compared to the average over the last day
- · Complex Event Processing
 - Correlation of events across different streams
 - $\bullet\,$ Emergency calls correlated with wind speed in real time

Comparing Databases with Real-Time systems

Approaches to Streaming

- Pure streaming
 - Each event is processed as it comes in
- · Micro-batch
 - Small batches of events are processed
 - Typically trades flexibility for performance
- · Shared nothing
 - You can process events on any system in the cluster
- · Stateful / Partitioned
 - The event must be processed on a system that has the correct state in memory

Data distribution

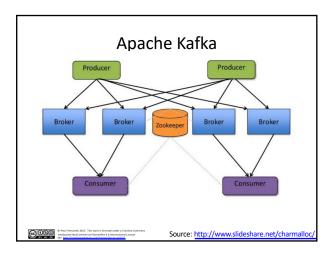

You need to get the events to the processing systems

MQTT (Message Queuing Telemetry Transport)

- Very simple, lightweight, fast
- No built in support for clustering / big-data
 - But can make up for it by being very fast
- Used a lot in IoT

Kafka

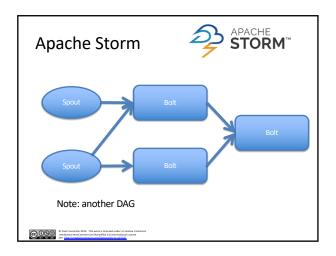

- Many of the approaches we've seen:
 - Partitioning
 - Multiple brokers
 - Elastically scalable
 - Supports clusters of co-ordinated consumers
 - Automatic re-election of leaders

Apache Storm

- Originally developed by BackType
 - Nathan Marz
- · Acquired by Twitter
- Open Sourced and then donated to Apache
- Became a top level project in 2014
 - http://storm.apache.org

Heron: Key Features

- Fully API compatible with Apache Storm
- Task isolation
- Developer productivity
- Ease of manageability
- Use of mainstream languages C++/Java/Python

Kafka Streams

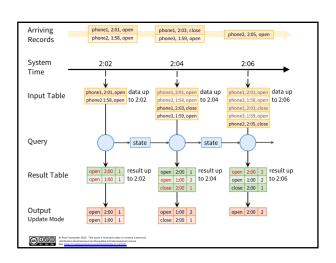

- Event-at-a-time processing (not microbatch) with millisecond latency
- Stateful processing including distributed joins and aggregations
- A convenient DSL
- Windowing with out-of-order data using a DataFlow-like model
- Distributed processing and fault-tolerance with fast failover
- Reprocessing capabilities so you can recalculate output when your code changes
- · No-downtime rolling deployments

Siddhi

- · A stateful query model
- SQL-like language for querying streams of data
 - Extended with windows
 - Time, Event count, batches
 - Partitioned
 - Based on data in the events
 - Pattern matching
 - A then B then C within window

© 000 0 Paul Fremantie 2015. This work is licensed under a Creative Common Attribution-NonCommercial-ShareAlike 4.0 International License

Siddhi at Uber

- 100+ production apps
- 30 billion messages / day
- · Fraud, anomaly detection
- · Marketing, promotion
- · Monitoring, feedback
- Real time analytics and visualization

Summary

- · Realtime processing is hard
 - Requires large memory and state
 - The lambda architecture splits the problem into batch and realtime challenges
- Multiple approaches:
 - Pure Streaming
 - Micro-batch
 - CEP
